Solving non-linear constraint satisfaction problems involving time-dependant functions

Aymeric Bethencourt and Luc Jaulin

Abstract. In this paper, we consider the resolution of non-linear constraint satisfaction problems where the variables of the systems are trajectories (functions from $\mathbb{R}$ to $\mathbb{R}^n$). We introduce the notion of tubes as intervals of functions, for which the lower and upper bounds are trajectories with respect to the inclusion. We then define basic operators and prove propositions verified by tubes. We show the possibility to build contractors on tubes and propagate constraints to solve problems involving time-dependant functions as the unknown variables. We show that the approach is particularly powerful when inter-temporal equations (e.g. delays) are involved. Finally, in order to illustrate the principle and efficiency of the approach, several test cases are provided.

1. Introduction

Interval analysis [1][2] has become over the past few years a strong alternative to traditional probabilistic approaches [3] to solve complex systems of equations, e.g. Simultaneous Localization And Mapping [4][5][6], 3D Reconstruction [7], path planning [8], or more generally the characterization of the state evolution of dynamic systems [9][10]. Interval analysis has been proven particularly efficient when the number of equations (namely constraints) is superior to the number of unknown variables [11]. The idea is to cast the system as a constraint satisfaction problem by considering intervals enclosing the solution and use contractors (built from the constraints) to successively contract these intervals until a fixed point is reached.

As more and more applications of Interval Analysis involve trajectories (functions from $\mathbb{R}$ to $\mathbb{R}^n$) [12], this paper will introduce the notion of intervals of trajectories (namely tubes), inspired from Taylor models [13], and define basic operations on tubes in section 2. We then show how to build contractors on tubes and demonstrate a few minimal contractors in section 3. We define the notion of Synchronous and Asynchronous constraints (constraints that involve inter-temporal relations) and show that our approach is particularly powerful for asynchronous constraints. Finally section 4 provides three non-linear test cases to illustrate the methodology, and section 5 concludes the paper.
2. Intervals of functions (or tubes)

In Interval Analysis, the unknown variables are usually boolean numbers, integers or real numbers, but the originality of this paper is to consider trajectories. In this section we consider the reader to be familiar with interval analysis [2]. We do however recall the basic notions of lattices and contractors that are used for working with tubes.

2.1. Lattices

A lattice \((E, \leq)\) is a partially ordered set, closed under least upper and greatest lower bounds [14]. The least upper bound of \(x\) and \(y\) is called the join or supremum and is denoted by \(x \vee y\). The greatest lower bound is called the meet or infimum and is written as \(x \wedge y\).

Example: The set \(\mathbb{R}^n\) is a lattice with respect to the partial order relation given by \(x \leq y \iff \forall i \in \{1, \ldots, n\}, x_i \leq y_i\). We have

\[
x \wedge y = (x_1 \wedge y_1, \ldots, x_n \wedge y_n)
\]

and

\[
x \vee y = (x_1 \vee y_1, \ldots, x_n \vee y_n)
\]

where \(x_i \wedge y_i = \min(x_i, y_i)\) and \(x_i \vee y_i = \max(x_i, y_i)\). A lattice \(\mathcal{E}\) is complete if for all (finite or infinite) subsets \(A\) of \(\mathcal{E}\), the least upper bound (denoted \(\vee A\)) and the greatest lower bound (denoted \(\wedge A\)) belong to \(A\).

Notice that the concept of lattice only works when using multidimensional intervals as set representation since \(\min()\) and \(\max()\) can only be defined element wise. This is not the case when using other set representations, such as e.g. ellipsoids [15].

2.2. Tubes

A Tube (or interval of a trajectory) [16] [17] is an set-membership vision of a random signal. The set \(\mathcal{F}^n\) of all functions from \(\mathbb{R}\) to \(\mathbb{R}^n\) is a complete lattice with partial order \(x \leq y \iff \forall t \in \mathbb{R}, x(t) \leq y(t)\). A tube \([x]\) is an interval \([x^-, x^+]\) of \(\mathcal{F}^n\), i.e., a pair of two trajectories \(x^-, x^+\) such that for all \(t\), \(x^-(t) \leq x^+(t)\). The set of all tubes of \(\mathcal{F}^n\) is denoted by \(\mathcal{II} \mathcal{F}^n\).
Solving non-linear constraint satisfaction problems involving time-dependant functions

An element \( x \) of \( \mathcal{F}^n \) belongs to the tube \([x]\) if \( \forall t, \ x(t) \in [x](t) \). Fig. 1 illustrates a function \( x \in \mathcal{F}^1 \) which is inside the tube \([x]\). This tube gives us information related to the unknown function \( x \).

If \( x \) is a function from \( \mathbb{R} \) to \( \mathbb{R}^n \) (i.e., \( x \in \mathcal{F}^n \)), we define
\[
[x](t) = \{ x(t), t \in [t] \}.
\]
Numerically, a tube \([x]\) is defined by
\[
[x](t) = \bigcup_{t \in [t]} [x](t),
\]
i.e., \([x](t)\) is the smallest box which encloses all boxes \([x](t), t \in [t]\). It is easy to prove that
\[
x \in [x], t \in [t] \Rightarrow x(t) \in [x](t),
\]
and that no box smaller than \([x](t)\) satisfies this property.

### 2.3. Tube arithmetic

We can extend operations on lattices to intervals of this lattice. The extension is the smallest interval which encloses all possible values. Therefore we can extend operations on \( \mathcal{F}^n \), such as sums, multiplication, image by a function, etc. to tubes. We use the rules of interval arithmetic and inclusion functions [1]. An arithmetic on tubes is thus a direct extension of interval arithmetic. As it is the case for interval computation, the result of an operation on tubes contains all results of the same operation performed on the enclosed elements of \( \mathcal{F}^n \).

**Integral.** Consider two numbers \( t_1, t_2 \) such that \( t_2 \geq t_1 \geq 0 \). The integral of a tube \([x]\) over an interval \([t_1, t_2]\) is defined [18] by
\[
\int_{t_1}^{t_2} [x](\tau) \, d\tau = \left\{ \int_{t_1}^{t_2} x(\tau) \, d\tau \text{ such that } x \in [x] \right\}.
\]
Since \( t_2 \geq t_1 \), we deduce from the monotonicity of the integral operator that
\[
\int_{t_1}^{t_2} [x](\tau) \, d\tau = \left[ \int_{t_1}^{t_2} x^- (\tau) \, d\tau, \int_{t_1}^{t_2} x^+ (\tau) \, d\tau \right].
\]
where \([x] = [x^-, x^+]\). From the definition of tube integrals, we have
\[
x \in [x] \Rightarrow \int_{t_1}^{t_2} x(\tau) \, d\tau \in \int_{t_1}^{t_2} [x](\tau) \, d\tau.
\]
Moreover, the interval primitive defined by \( \int_{0}^{t} [x](\tau) \, d\tau \) defines a tube that vanishes for \( t = 0 \).

**Extension of operators.** If \( \odot \) is a binary operator in \( \mathbb{R}^n \) (such as \( +, - \), the multiplication \( * \) when \( n = 1 \) or the vector product when \( n \geq 2 \)) then it can be extended to \( \mathcal{F}^n \) (in the Minkowski sense) and to \( \mathbb{R}^n \) as follows
\[
A \odot B = \{ a \odot b, a \in A, b \in B \}
\]
From the monotony of the operator, we have
\[
[x] \odot [y] = [\lor (x) \odot [y]), \land (x) \odot [y])] \quad (2.9)
\]
E.g., for \([x]\) and \([y]\) \in \mathcal{F}^n \) and \( a \in \mathbb{R}^+ \)
\[
(i) \quad [x] + [y] = [x^+, x^− + y^−] \\
(ii) \quad a[x] = [ax^−, ax^+ + ay^+] \quad (2.10)
\]
**Tube envelope.** Consider a collection \( \{ f_i, i \in \mathbb{N} \} \) of functions. The tube envelope \( \square \{ f_i, i \in \mathbb{N} \} \) is the smallest tube enclosing all \( f_i \). We have
\[ \square\{f_i, i \in \mathbb{N}\} = [\forall i \in \mathbb{N} f_i; \land i \in \mathbb{N} f_i] \]  

(2.11)

For instance,

\[ \text{for } t \in [0, \infty], \square\{t, \cos(t), -1\} = [-1; t] \]  

(2.12)

**Inclusion.** We define the tube inclusion as follows

\[ [x] \sqsubset [y] \iff y^- \leq x^- \leq x^+ \leq y^+ \]  

(2.13)

**Intersection.** We define the tube intersection as follows

\[ [x] \cap [y] \iff [x] \lor [y]; [x] \land [y] \]  

(2.14)

### 2.4. Constraint propagation on tubes

**Tube contractor.** Consider a constraint \( L(x) \) on a trajectory \( x \). A contractor associated with the constraint \( L \) is an operator

\[ [y] \xrightarrow{C_L} [x] \]  

(2.15)

where \([x]\) and \([y]\) are tubes, such that

\[ \forall t, [x](t) \subset [y](t) \quad \text{(contraction)} \]

\[ L(x) \quad \text{such that } x \in [x] \quad \Rightarrow x \in [y] \quad \text{(completeness)} \]  

(2.16)

We call \( C^* \) the minimal contractor for \( L \) that returns the tube \([y]\) with the smallest width and is consistent with the constraint \( L \).

Many problems of estimation, control, robotics, etc. can be represented as constraint satisfaction problems (CSP) [19],[20] and many minimal contractors can be applied to optimally contract the domains depending on the class of the problem [11]. Several minimal contractors have been developed over the years: Gauss elimination, Gauss-Seidel Algorithm, Krawczyk method, Newton algorithm, etc. [2].

We can also propose minimal contractors for tubes, but let us first separate our constraints into two categories:

- Synchronous constraint: Constraint that is set to happen at the same time, typically \( x(t) = y(t) \) is synchronous.
- Asynchronous constraint: Constraint that is set to happen at different times, typically \( x(t) = y(t - 2) \) is asynchronous. This requires to have the history of the variable \( y \) and this is where tubes will be particularly powerful.

We are now proposing a few minimal contractors for both types.

**Proposition 1.** The minimal contractor associated with the synchronous constraint \( x \leq y \) or \( \forall t \in [0, \infty[, x(t) \leq y(t) \) is

\[ C_\leq \left( \begin{array}{c} [x] \\ [y] \end{array} \right) = \left( \begin{array}{c} [x^-; x^+ \land y^+] \\ [x^- \lor y^-; y^+] \end{array} \right) \]  

(2.17)
Solving non-linear constraint satisfaction problems involving time-dependant functions

**Figure 2.** (a) represents the trajectory \( x \) and its tube \([x]\), (b) the trajectory \( y \) and its tube \([y]\), and (c) illustrates the meet and join of them.

**Proof.** \( x \preceq y \) so according to the independence theorem, we can find \( a \) such that \( y = x + a \) with \( a \geq 0 \). We can therefore contract the associated tube.

\[
[y] = [y] \cap ([x] + [a])
\]

\[
\iff [y] = [y^- \vee (x^- + a^-), y^+ \land (x^+ + a^+)]
\]

\[
\iff [y] = [y^- \vee (x^- + 0), y^+ \land (x^+ + \infty)]
\]

\[
\iff [y] = [y^- \vee x^-, y^+]
\]

since \( [a] = [0, \infty] \). By considering \( x = y + a \) with \( a \leq 0 \), we can prove that \([x] = [x^-, x^+ \land y^+]\) the same way.

Figure 2 illustrates the contractions.

**Proposition 2.** The minimal contractor associated with the synchronous constraint \( x = y \) (which means that \( \forall t \in [0, \infty], x(t) = y(t) \)) is

\[
C_x \left( \begin{array}{c} x \\ y \end{array} \right) = \left( \begin{array}{c} [x^- \vee y^-, x^+ \land y^+] \\ [x^- \vee y^-, x^+ \land y^+] \end{array} \right)
\]

**Proof.** As \( x = y \), any given elements of \( x \) and \( y \) cannot exceed each other’s range. Both variables will share a new interval equal to the intersection of their respective intervals.
\[ [x] = [x] \cap [y] \]
\[ \leftrightarrow [x] = [x^- \vee y^-, x^+ \wedge y^+] \]

The same is proven for \( y \).

**Proposition 3.** The minimal contractor associated with a translation or delay \( \forall t \in [0, \infty[, x(t) = y(t - \tau) \) is

\[
C_{\text{delay}} \left( \begin{bmatrix} x \\ y \end{bmatrix} \right) = \left( \forall t, \begin{bmatrix} x^-(t) \vee y^-(t - \tau), x^+(t) \wedge y^+(t - \tau) \\ x^-(t + \tau) \vee y^-(t), x^+(t + \tau) \wedge y^+(t) \end{bmatrix} \right)
\]

**Proof.** The proof is immediate considering Proposition 2.

Fig. 3 illustrates this notion. The purple area represents the tube \([x^-(t) \vee y^-(t - \tau), x^+(t) \wedge y^+(t - \tau)]\).

Let us notice that this constraint is asynchronous as it involves two different times: \( t \) and \( t - \tau \).

**Special case.** If the constraint is \( x(t) = x(t - \tau) \), then \( x \) is \( \tau \)-periodic and \( \forall k \in \mathbb{N}, C_{\text{periodic}}([x]) = ([x^-(t) \vee x^-(t - k\tau), x^+(t) \wedge x^+(t - k\tau)]) \).

**Proposition 4.** The minimal contractor associated with an axial symmetry around the axis \( t = \tau \) is

\[
C_{\text{ASym}} ([x(\tau + t)]) = [x^-(\tau + t) \vee x^-(\tau - t); x^+(\tau + t) \wedge x^+(\tau - t)]
\]

**Proof.** Let’s define the axial symmetry operator \( S \) such that \( S(f(\tau + t)) = f(\tau - t) \). \( S \) is increasing since

\[
f(\tau + t_1) \leq f(\tau + t_2)
\]
\[ \leftrightarrow S(f(\tau + t_1)) \leq S(f(\tau + t_2)) \]
\[ \leftrightarrow f(\tau - t_1) \leq f(\tau - t_2) \]

Moreover,

\[
[x(\tau + t)] = [x^-(\tau + t), x^+(\tau + t)]
\]
\[ \leftrightarrow S([x(\tau + t)]) = [S(x^-(\tau + t)), S(x^+(\tau + t)))] \]
\[ \leftrightarrow S([x(\tau + t)]) = [x^-(\tau - t), x^+(\tau - t)] \]

Therefore \( C_{\text{ASym}} ([x(\tau + t)]) = [x(\tau + t)] \cap S([x(\tau + t)]) = [x^-(\tau + t) \vee x^+(\tau - t); x^+(\tau + t) \wedge x^+(-t)] \)

**Special case :** When \( \tau = 0 \), then \( x \) is even and \( C_{\text{even}} ([x(t)]) = [x^-(t) \vee x^-(t); x^+(t) \wedge x^+(-t)] \)

Fig. 4 illustrates this case.

**Proposition 5.** The minimal contractor associated with a central symmetry around the axis \( t = \tau \) is

\[
C_{\text{CSym}} ([x(\tau + t)]) = [x^-(\tau + t) \vee (-x^+(\tau - t)); x^+(\tau + t) \wedge (-x^-(\tau - t))] \]

**Proof.** The proof is identical to proposition 4 considering \( S \) decreasing.

**Special case :** When \( \tau = 0 \), then \( x \) is odd and \( C_{\text{odd}} ([x(t)]) = [x^-(t) \vee (-x^+(t)); x^+(t) \wedge (-x^-(t))] \)

Notice that both symmetries are asynchronous constraints.
FIGURE 3. Asynchronous constraint propagation on tubes.
2.5. State estimation

The problem to be considered in this section is the state estimation of a non-linear continuous-time systems in a bounded error context. Usually we describe the system as follows:

\[ \dot{x}(t) = f(x(t)) \]
\[ y(t) = g(x(t)) \]  

(2.26)

where \( t \in [0, \infty) \) is the time, \( x(t) \in \mathbb{R}^n \) and \( y(t) \in \mathbb{R}^n \) are respectively the state and the output vectors at time \( t \), and \( f \) and \( g \) the evolution and observation functions. To solve the state estimation problem, many efficient methods can be found in the literature when \( f \) and \( g \) are linear [21][22]. When \( f \) is non-linear, there are only to our knowledge a few approaches [23][24][25] that propose an efficient state estimation.

The originality of our approach is to consider that \( g \) is no longer the observation function at a given state, but a relationship between two states of the system at different times. \( g \) is therefore an inter-temporal equation between the state of the system at time \( t_1 \) and its state at time \( t_2 \).

(2.26) becomes

\[ \dot{x}(t) = f(x(t)) \]
\[ y(t_1, t_2) = g(x(t_1), x(t_2)) \]  

(2.27)

This representation allows us to express inter-temporal constraints, and use them to solve time-dependent problems as presented in the next section. An alternative solution is to formulate the inter-temporal constraints in the framework of DAEs (Differential Algebraic Equations). Reachability analysis of DAE systems has already been considered in [26] and [27]. In our approach, we propose the following way to solve such systems. We first start with a with a large tube enclosing \( x \) and contract \( [x] \) for all \( t \) using the output vectors, i.e. \( y(t_1, t_2) \) will contract \( [x](t_1) \) and \( [x](t_2) \). We then
apply a variant of the STRANGLE and CONTRACT algorithms from [23]. We first apply the STRANGLE around a time \( k_0 \) given an initial interval \([x_0]\) and a precision \( \epsilon \). This algorithm bisects the interval \([x_0]\) into two sub-intervals and propagates each sub-interval using the CONTRACT algorithm. If the contraction of the tube \([x]\) with the sub-interval possesses empty intervals, then the sub-interval does not contain the solution and we discard it. If the tube has no empty interval, then the sub-interval contains the solution and we bisect it again by recursively calling CONTRACT until the precision is reached. We then take the union of all the tubes that possess no empty interval. This union is guaranteed to contain the solution.

The CONTRACT algorithm uses the operator \([\phi]\) as defined in [23] to compute enclosures of the state vector at times \( \delta, 2\delta, \ldots, k\delta \) where \( \delta \) is the sampling time and \( k \) is the largest integer smaller than \( t/\delta \), from a given box \([x]\) containing \( x \). \( t \) is the end time of the problem. \([\phi]\) is the operator for the time increasing and computes the state of the system at time \( k + 1 \) from \( k \). \([\bar{\phi}] \) is the operator for the time decreasing and computes the state of the system at time \( k + 1 \) from \( k + 1 \). For the sake of simplicity in the following examples, we are using a basic Euler method for \([\phi]\) and thus for solving the ODE and computing the successive states of the system. Notice that using an Euler method means that we lose the guarantee in the results below but do not impact the proof of concept presented in this article. Moreover, there exists multiple libraries for computing rigorous bounds on the solution of ordinary differential equations, e.g. VNODE [28] and multiple methods especially developed for studying the evolution of dynamic systems [29].

### 3. Examples

#### 3.1. Example 1: Sinusoidal signal

Let’s consider an unknown signal \( a(t) \) where \( t \) is the time. We consider to know only a few properties about \( a \) and want to find the smallest tube enclosing the solution. For example, let us consider that \( a \) verifies:

TABLE 1. Contract algorithm

```plaintext
Algorithm C_{CONTRACT} (in: \( k_0 \), \([x_0]\), inout: \([x]\))
1 for \( k := 0 \) to \( k \)
  2 if(\( k == k_0 \))
    3 \([x](k) = [x_0];
    4 endif
  5 \([x](k + 1) = [x](k + 1) \cap [\phi](\([x](k), [\dot{x}](k)\));
  13 endfor
14 for \( k := k \) to 0
  15 if(\( k == k_0 \))
    16 \([x](k) = [x_0];
    18 endif
  19 \([x](k) = [x](k) \cap [\bar{\phi}](\([x](k + 1), [\dot{x}](k + 1)\));
  26 endfor
```
Algorithm $C_{\text{STRANGLE}}$ (in : $k_0, [x_0], \epsilon$, inout : $[x]$)

1. if $([x_0].\text{width} > \epsilon)$
2. $Bisect([x_0], [x_1], [x_2])$;
3. $[z] = \text{CONTRACT}(k_0, [x_1], [x])$
4. if $([z]$ has no empty interval)
5. $\text{CONTRACT}(k_0, [x_1], [z])$;
6. endif
7. $[z] = \text{CONTRACT}(k_0, [x_2], [x])$
8. if $([z]$ has no empty interval)
9. $\text{CONTRACT}(k_0, [x_2], [z])$;
10. endif
11. else
12. $[z] = \text{CONTRACT}(k_0, [x_0], [x])$
13. if $([z]$ have no empty interval)
14. $[x] = [x] \sqcup [z]$;
15. endif
16. endif
17. return $[x]$

Table 2. Strangle algorithm

\[
\begin{align*}
 a([−\infty; \infty]) & \subset [−1; 1] \quad (3.1) \\
 a([\pi/2, \pi]) & \subset [−0.7(t - \pi/2) + 0.99, -0.1(t - \pi/2) + 1.01] \quad (3.2) \\
 a(t + \pi) & = -a(t) \quad (3.3) \\
 a(t + 2\pi) & = a(t) \quad (3.4) \\
 b(t - \pi/2) & = a(t) \quad (3.5) \\
 b(t) & = \dot{a}(t) \quad (3.6) \\
\end{align*}
\]

We first define the tube $[a](t) = [a^−(t), a^+(t)] = [−\infty, \infty]$ then apply contractors 3.1 and 3.2. Each inclusion represents two contractors. For instance, 3.2 is equivalent to

\[
\forall t \in [\pi/2, \pi], \quad a(t) \leq -0.1(t - \pi/2) + 1.01 \quad (3.8)
\]

Therefore, we apply the superiority contractor presented in section 3. The result is presented Fig. 5(a). Contractors 3.4 and 3.5 respectively shows that our signal is symmetrical with respect to the point $(\pi, 0)$ and is $2\pi$ periodic. Results of these contractions are presented Fig. 5(b) and Fig. 5(c).

Then we apply the time delayed contractor from 3.6 to create a new tube $b$:

\[
[b(t)] = [b(t)] \cap [a(t + \pi/2)] \quad (3.9)
\]

Finally, from the differential equation 3.7, we can integrate $[b]$ and contract $[a]$ using the equality contractor:
Figure 5. Successive contraction of the tube $a$.

\begin{equation}
[a(t)] = [a(t)] \cap \left[ \int_{\tau=0}^{t} \frac{dB^{+}(\tau)}{dt} d\tau - \int_{\tau=0}^{t} \frac{dB^{-}(\tau)}{dt} d\tau \right]
\end{equation}

The results is illustrated in Fig. 5(d). To contract the tube even more, we can re-apply all the contractors one time (Fig. 5(e)), three times (Fig. 5(f)), five times (Fig. 5(g)) or even ten times (Fig. 5(h)) until the width of the tube is satisfying or until a fixed point is reached. We then clearly recognize the sine signal.
3.2. Example 2: Non-linear mass-spring system

Let us now consider an example based on the famous academic problem that is the mass-spring system presented in Fig. 6. In actual systems, there is a progressive stiffening or weakening of the spring as it is elongated or compressed. This causes the response of the system to be nonlinear. Its dynamic is given by Newton’s second law.

\[
m\ddot{x} + \gamma \dot{x} + \kappa x - \beta x^3 = 0
\]  
\[\text{(3.11)}\]

where \(\beta\) is the stiffness of the spring, \(m\) is the mass, \(x\) is the displacement, \(\kappa\) is the spring elasticity and \(\gamma\) is the damping constant.

Knowing the initial conditions, this system could be easily solved using standard numerical methods. However, the particularity of our approach is to consider that we do not know the initial conditions. In return, we equip the mass with a sonar that sends a ping every second. We consider the sound wave sent at \(t_1\) to travel at \(c = 100\text{m.s}^{-1}\) to the right wall, where it is reflected and received back to the sonar at \(t_2\). In our simulation, we place the right wall at \(L = 10\text{m}\). This means that the mass moves significantly between the emission and the reception of pings. Each ping is represented by an inter-temporal equation:

\[
(L - x(t_1)) + (L - x(t_2)) = c(t_2 - t_1)
\]
\[
\iff x(t_2) + x(t_1) = 2L - c(t_2 - t_1)
\]  
\[\text{(3.12)}\]

To our knowledge, we cannot easily solve this nonlinear system with standard numerical methods. We thus consider this problem as a state estimation problem of a nonlinear delayed system and use our constraint propagation approach defined in the previous section. We first rewrite the system as state equations:

\[
\frac{d}{dt} \begin{pmatrix} x \\ \dot{x} \end{pmatrix} = \begin{pmatrix} \ddot{x} \\ (\beta x^2 - \kappa) \dot{x} - \gamma \dot{x} \end{pmatrix} \quad \text{(Evolution equation)}
\]
\[
x(t_i) + x(t_j) = 2L - c(t_i - t_j) \quad \text{(Observation equations)}
\]  
\[\text{(3.13)}\]
Solving non-linear constraint satisfaction problems involving time-dependant functions

where the $t_j$ are sending times and $t_i$ receiving times. Each ping represents an asynchronous constraint that translates into a contractor for $[x]$ and $[\dot{x}]$.

We developed a simulator using MATLAB’s Ode45 and defined an initial state with the evolution equations. The result is presented Fig.7. We then simulated sonar pings every seconds. We also simulated errors in the measurements up to $+/-0.05m$ to stay consistent with guaranteed results. We also purposefully “lost” a few pings to simulate sporadic measurements. For the sake of transparency, we used $m = 8kg$, $\gamma = 1$, $\kappa = 2$, $\beta = -0.5$ and $L = 100m$. Initial conditions are $x_0 = 10m$ and $\dot{x}_0 = 0m.s^{-1}$. The simulated sonar output has the following form:

$$
x(3.00) + x(3.48) = 34.33
$$

$$
x(9.00) + x(9.54) = 15.46
$$

$$
x(12.00) + x(12.55) = 13.06
$$

$$
x(20.00) + x(20.51) = 24.38
$$

etc.

As we are using a simple Euler method, 3.13 numerically becomes:

$$
x(k + 1) = x(k) + dt.\dot{x}(k)
$$

$$
\dot{x}(k + 1) = \dot{x}(k) + dt.\left(\frac{\beta x^2(k) - \kappa).x(k) - \gamma.\dot{x}(k)}{m}\right)
$$

$$
x(i) + x(j) - l = 0
$$

where $l = 2L - c.\left(i - j\right)$ which is a small measured interval. Therefore we have:

$$
x(j) = x(j - 1) + dt.\dot{x}(j - 1)
$$

$$
= x(j - 2) + dt.\dot{x}(j - 2) + dt.\dot{x}(j - 1)
$$

$$
= x(j - 3) + dt.\dot{x}(j - 3) + dt.\dot{x}(j - 2) + dt.\dot{x}(j - 1)
$$

$$
= x(i) + dt.\sum_{k=i}^{j-1} \dot{x}(k)
$$

and

$$
x(j) - x(i) = v
$$

$$
x(j) + x(i) = l
$$

where $v = \sum_{k=i}^{j-1} \dot{x}(k)$ which is equivalent to

$$
x(i) = \frac{1}{2}(l - v)
$$

$$
x(j) = \frac{1}{2}(l + v)
$$

To sum up, we have the following contractors:

- State equation. Tubes $[x]$ and $[\dot{x}]$, contracted using the evolution equation from 3.13:
\[
[\dot{x}(t)] = [\dot{x}(t)] \cap \int_{\tau=0}^{t} \left[ \frac{(\beta x^2 - k) x - c \dot{x}}{m} \right] (\tau) d\tau
\] (3.20)

\[
[x(t)] = [x(t)] \cap \int_{\tau=0}^{t} [\dot{x}] (\tau) d\tau
\]

- Movements. Using the speed tube [\dot{x}] of the mass, we can compute all the \(n_{\text{max}}\) variables \(v_n = dt. \sum_{k=i_n}^{j_n-1} \dot{x}(k)\), where \(n\) corresponds to the \(n\)-th sonar emission and \(v_n\) corresponds to the movement of the mass between the \(n\)-th sonar emission and \(n\)-th sonar reception. We have the following contractor:

\[
[v_n] = [v_n] \cap dt. \sum_{k=i_n}^{j_n-1} [\dot{x}](k)
\] (3.21)

- Positions. From 3.19, we get two more contractors:

\[
[x](i_n) = [x](i_n) \cap \frac{1}{2} ([l_n] - [v_n])
\] (3.22)

\[
[x](j_n) = [x](j_n) \cap \frac{1}{2} ([l_n] + [v_n])
\]

We present in table 3 and 4 the CONTRACT and STRANGLE algorithms modified specifically for this example. Given an initial tube for \([x]\) and \([\dot{x}]\), the algorithm STRANGELE2 will apply the contractors 3.21 and 3.22, 3.20. The algorithm imposes intervals \([\text{box}](1)\) to \([x]\) and \([\text{box}](2)\) to \([\dot{x}]\) when the time reaches \(k_0\) and propagates the intervals forward then backward along the tubes according to the states equations. If the contracted tubes contain empty intervals, the given \text{box} at \(k_0\) does not contain the solution. In this case, we discard the given \text{box} (white area on Fig.9). If the contracted tubes have no empty interval, then the tubes might contain the solution, and we keep it stored in memory (blue area on Fig.9). In the end, we take the union of all non-empty tubes. The union contains the solution.

Table 3 presents the algorithm where \(\phi_1([x](k), [\dot{x}](k))\) is the numerical estimation method of the state equation 3.13. For instance, using an Euler method, \(\phi_2([x](k), [\dot{x}](k)) = \frac{1}{2} [x][k] + dt. \left[ \frac{x}{t^2}[k] - k_0 \frac{1}{m} [\dot{x}][k] - \gamma [\dot{x}][k] \right].\) Again, the result can be guaranteed using more complex methods and/or VNODE. Our algorithm is only guaranteed in respect to the numerical estimation method used. Because of the wrapping effect on each step of the propagation, the tubes \([x]\) and \([\dot{x}]\) rapidly explode. It is therefore impossible to contract efficiently the tubes from beginning \((k_0 = 0)\) to end \((k_0 = k)\) in one passing. We therefore bisect \text{box} until a required width is reached and use CONTRACT2 to contract the tubes. We define \text{box} = ([x](k_0), [\dot{x}](k_0)) and apply the iterative algorithm proposed in table 4 to bisect, propagate and take the union of the non-empty tubes until the required precision is reached.

Fig.8 shows the result of the algorithm. (1p) represents the position tube \([x]\) after applying the contractors 3.22 and (1v) represents the speed tube \([\dot{x}]\). (2p) and (2v) represent the same tubes after applying STRANGEL2 for \(k_0=0s\), (3p) and (3v) for \(k_0=0s\), \(k_0=25s\) and \(k_0=50s\). The final result is shown in (4p) and (4v) for which STRANGEL2 is applied every \(t\%5 = 0s\).
Notice that if the inter temporal constraints are posed such that the problem is infeasible, the solution set becomes empty. Computation time for this example on a single core 3.2 Ghz processor is on average 2.5s.

### 3.3. Example 3: Group of AUVs

For the last example, let us consider a group of robotic *Autonomous Underwater Vehicles* (AUVs). When not submerged, the AUVs are able to use the *Global Positioning System* to accurately compute their position. However, when they are underwater, they can no longer use the GPS and have to estimate their position using their state equations. To illustrate the method, we developed a 3D simulator that generates a set of data from a simulated group of 6 robots following given trajectories.
Algorithm $C_{\text{STRANGLE}}^2$ (in : $\epsilon, [k0], [box]$, inout : $[x], [\dot{x}]$)

1. if(box.width > $\epsilon$)
2.  Bisect([box], [subbox1], [subbox2]);
3.  $([z], [\dot{z}]) = CONTRACT^2([subbox1], [z], [\dot{z}])$
4.  endif
5.  $([z], [\dot{z}]) = CONTRACT^2([subbox2], [z], [\dot{z}])$
6.  endif
7. else
8.  $([z], [\dot{z}]) = CONTRACT^2([box], [z], [\dot{z}])$
9.  endif
10. $[x] = [x] \sqcup [z]$;
11. $[\dot{x}] = [\dot{x}] \sqcup [\dot{z}]$;
12. endif
13. return ($[x], [\dot{x}]$)

| Table 4. Strangle algorithm for Ex. 2 |

\begin{align}
V_i \in \{1, 2, 3\}, \dot{x}_i &= \begin{pmatrix} 100 \sin t \\ 100 \cos t \\ (10 \cos t) - 10 \end{pmatrix} \\
V_i \in \{4, 5, 6\}, \dot{x}_i &= \begin{pmatrix} 100 \sin t \\ 100 \cos t \\ (10 \cos t) - 30 \end{pmatrix}
\end{align}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{image}
\caption{MATLAB’s Ode45 solution.}
\end{figure}
We assume that the state of each AUV is described by the following equations:

\[
\begin{align*}
\dot{x}_1 &= u_1 \cos u_2 \\
\dot{x}_2 &= u_1 \sin u_2
\end{align*}
\]  

(3.25)

where the speed \(u_1\) and heading \(u_2\) are measured every 0.01s for a duration of 100s. The initial state is not known. Because of the noise in the measurements, the uncertainty of the state is increasing over time. The estimated position is represented by a box enclosing the real position.
of the AUV. This box is obviously very thin when the AUV uses the GPS, then gets bigger and bigger underwater. The idea is to contract these boxes when two or more AUVs are in range of communication with each other. We equipped each submarine with a sonar that can broadcast the estimated position box of the AUV every second. The originality of this example is to consider that the displacement of the robot while the sonar wave is moving is superior to the precision of the localization. Therefore we cannot suppose that we measure a true distance between AUVs at the same time, but between AUVs at different times. Note that the communication is one-way only and does not have to be synchronized between the AUVs. When AUV $i$ received at $t_i$ a sonar ping from robot $j$ emitted at $t_j$, we get a constraint of the form:

$$|| \mathbf{p}_i(t_i) - \mathbf{p}_j(t_j)|| = c.(t_i - t_j) \quad (3.26)$$

where $c$ is the celery of the sound in water and $\mathbf{p}_i$ is the position vector of a submarine $i$ in x-y-z coordinates. This way, we have a system of constraints similar to example 2. Fig.10 presents the 3D simulator developed to generate the constraints for each AUV.

$\text{etc.}$

Using the same approach than for example 2, we can solve this problem using constraint propagation on tubes. Fig. 11 shows the result of the contractions for the position $x$ of one AUV.

Computation time for this example on a single core 3.2 Ghz processor is on average 15 ms for all AUVs. Finally, we can further consider a more realistic model where the clocks of the AUVs are
unsynchronized, meaning that the constraints are defined on uncertain times. [30] shows that it is still possible to easily solve the problem.

4. Conclusion

Solving nonlinear systems involving differential equations is a difficult problem, especially when the initial conditions are unknown or when the problem is ill-conditioned, e.g. involving inter-temporal measurements. To numerically solve this class of problems, this paper has first introduced the notion of tube which encompasses the informations needed to guarantee associations upon trajectories. Then, an arithmetic was developed around this notion, and a contractor-based approach has been followed. As a result, a method has been proposed to contract tubes that enclose the solution. Further work will include the study of outliers and the study of the scalability of the approach when applied to a swarm of hundreds of AUVs [31]. As most interval-based methods, this approach can be combined with probabilistic methods [10] and made robust with respect to outliers by relaxing a given number of constraints [12].

Finally, in order to share our research with the community, we integrated tubes, their properties, operators and minimal contractors presented below with IBEX (Interval Based EXplorer), a powerful library for interval computation. You can download IBEX and all the source codes for the examples presented in this article on http://AymericBethencourt.com/tubes/
